MAGNETIZATION TRANSFER: THEORY

In NMR, MT (magnetization transfer) is a general term that describes the process of magnetization transfer from one spin population to another

- ❑ In MRI, MTC (**Magnetization Transfer Contrast**) denotes saturation transfer contrast originating from semi-solid macromolecules (large protein, collagen, myelin) or bound water protons with broad lineshapes (short T_2 10-100 μ s)
- ❑ In MRI, CEST (**Chemical Exchange Saturation Transfer**) denotes saturation transfer by chemical exchange originating from mobile proteins (long $T_2 > 10$ ms) and metabolites (or exogeneous contrast agents)

- Selective magnetic labeling of a proton pool that is stored as a change in longitudinal magnetization
- Transfer of this label to a water proton pool
- Accumulation of the label for the purpose of water signal reduction

MTC AND CEST

- Labelling proton pools of the semisolid macromolecular component (spin-diffusion or cross-relaxation) followed by transfer to solvent water protons by means of bound water (dipolar coupling or chemical exchange)

- Labelling of mobile protons downfield from water (chemical exchange)

- Labelling of aliphatic proton in mobile proteins upfield from water (relayed NOE)

MAGNETIZATION TRANSFER CONTRAST

$$\text{MTR} = 1 - S_{\text{sat}}/S_0$$

Applications:

- magnetic resonance angiography (MRA) to enhance signal contrast between the blood and other tissue
- Characterization of white matter disease in the brain, principally demyelination disease (multiple sclerosis) or for assessing knee cartilage

Limitations:

- sensitivity, specificity, and reproducibility of MTR measures can be influenced by various experimental parameters and field strength
- MTR measures tend to reflect a complex combination of sequence details and relaxation parameters

Longitudinal assessment of mouse renal injury using high-resolution anatomic and magnetization transfer MR imaging☆

Feng Wang ^{a,b}, Rosie Jiang ^e, Keiko Takahashi ^e, John Gore ^{a,b,c,d}, Raymond C. Harris ^e, Takamune Takahashi ^{d,e,*}, C. Chad Quarles ^{a,b,c,d,**}

- Obstructive nephropathy is a primary source of renal impairment in infants and children
- The Unilateral Ureteral Obstruction (UUO) model in mice induces serial changes in renal structure and recapitulates key features of tubular damage, apoptosis, and renal fibrosis
- **The decreased MTR values suggest reduced macromolecular content, which could be related to apoptosis, tubular atrophy and urine retention**

Noninvasive Assessment of Renal Fibrosis with Magnetization Transfer MR

Imaging: Validation and Evaluation in
Murine Renal Artery Stenosis¹

- Renal artery stenosis (RAS) decreases renal blood flow (RBF) and causes a progressive loss of renal mass and function.
- Kidney undergoes a progressive deposition of extracellular matrix components (fibronectin and collagen type I, III, and IV) which may evolve into tubulointerstitial fibrosis.

16.4T, RF @2.1 ppm, 10 μ Tx80ms

Assessment of renal fibrosis in murine diabetic nephropathy using quantitative magnetization transfer MRI

Feng Wang^{1,2*} | Daisuke Katagiri^{3*} | Ke Li¹ | Keiko Takahashi³ | Suwan Wang³ |
Shinya Nagasaka^{3,4} | Hua Li^{1,2} | C. Chad Quarles^{1,2} | Ming-Zhi Zhang³ |
Akira Shimizu⁴ | John C. Gore^{1,2} | Raymond C. Harris³ | Takamune Takahashi³

- Diabetic nephropathy (DN) is a major diabetic complication
- Renal fibrosis is a hallmark of progressive kidney disease, including DN
- db/db mice that lack the eNOS gene exhibit advanced DN similar to that found in human DN

Wild-type (9-week)

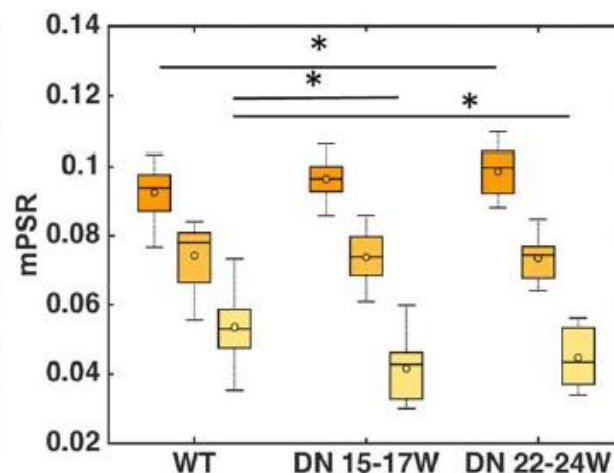

db/db -eNOS^{-/-} (24-week)

Henkelman-Ramani's model:

$$SI(\omega_1, \Delta f) = \frac{M_0 \left(R_b \left[\frac{RM_{0b}}{R_a} \right] + R_{RFB}(\omega_{1CWPE}, \Delta f, T_{2b}) + R_b + \frac{RM_{0b}}{F} \right)}{\left[\frac{RM_{0b}}{R_a} \right] \left(R_b + R_{RFB}(\omega_{1CWPE}, \Delta f, T_{2b}) \right) + \left(1 + \left[\frac{\omega_{1CWPE}}{2\pi\Delta f} \right]^2 \left[\frac{1}{T_{2a}R_a} \right] \right) \left(R_{RFB}(\omega_{1CWPE}, \Delta f, T_{2b}) + R_b + \frac{RM_{0b}}{F} \right)}$$

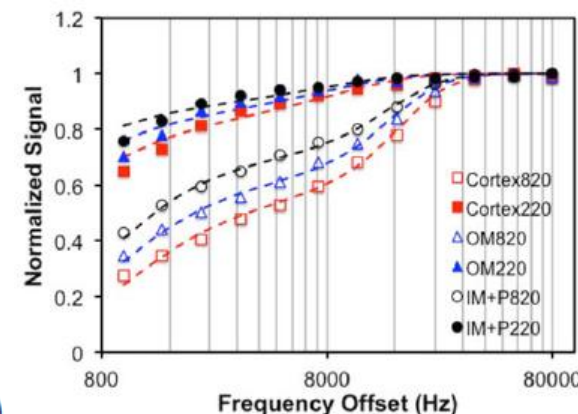

F = relative size of the macromolecular pool (PSR)

Cortex: increased fibrosis

OM, IM+P: urine retention

Cortex (dark orange)
OM (light orange)
IM+P (yellow)

KIDNEY REGULATION OF ACID-BASE HOMEOSTASIS

- ❑ The kidneys play a major role in the regulation of acid-base balance by reabsorbing bicarbonate filtered by the glomeruli and excreting titratable acids and ammonia into the urine
- ❑ Decline in kidney function will result in derangements in acid-base homeostasis with reduced ammonia excretion, inability to reabsorb bicarbonate and failure of acid excretion when kidney function is severely impaired
- ❑ In chronic kidney disease (CKD), with declining kidney function, acid retention and metabolic acidosis occur
- ❑ Degree of acidosis approximately correlates with severity of renal failure and usually is more severe at a lower GFR
- ❑ Several adverse consequences have been associated with metabolic acidosis, including muscle wasting, bone disease and progression of renal failure

Renal pH mapping may represent a novel biomarker for detecting (early) renal damage

Iopamidol as a Responsive MRI-Chemical Exchange Saturation Transfer Contrast Agent for pH Mapping of Kidneys: In Vivo Studies in Mice at 7 T
